24 Field Application of Foul-Release Coating

By Sang Ki Chi, Seung Hyun Kim, and Byung Wan Kim

Institute of Industrial Technology, Samsung Heavy Industries Co., Ltd.

To capitalize on the environmental and cost benefits of employing silicone foul-release coatings for marine and offshore use, the authors conduct a study that demonstrates how to avoid potential field application problems.

31 2014 Annual Equipment Buying Guide

This year's Equipment Buying Guide lists products, equipment, and supplies for protective and marine coating work from nearly 500 manufacturers, distributors, and rental companies located around the world. Product listings begin on p. 35, and contact information for each company begins on p. 107. As in previous years, the Equipment Buying Guide is based on surveys completed by equipment companies known to JPCL.

Time to Take a Break

The summer months are finally here, and many of us have had to put up with one of the worst winters of cold, snow, and ice that we have had in many years. The daily grind of coming to the office, going on business trips, and dealing with the normal day-to-day challenges we face can wear us all down. We need to take a break, yet many of us fail to take the vacation days we are allotted each year. A nice long vacation of 10 days to two weeks would be best.

I am guilty of this flaw in my lifestyle and always have been throughout my entire working career. In my previous job, we were given 30 days off a year. In that profession, Saturdays and Sundays counted against that allotment, so we did not get six weeks, as many people would assume. Still, I never took my total authorized days, and I'm sure I paid a price for that with the increased stress and anxiety that the workplace caused. In that organization, it was so routine to lose vacation days that the senior leadership instituted a policy where the boss would be "counseled" by his superiors if his subordinates did not take their allotted time off. So what I did was recorded vacation days even when I was at work. My boss condoned what I was doing because he did the same thing, and he knew I did not want to get him in trouble. He appreciated my loyalty to him and the organization.

The bottom line was that I thought I was invaluable to the organization, and I honestly felt guilty when I took time off. I thought I had to be there to get ahead. Now that I look back, I think the organization would have done quite well without me, and I can attest that the organization was far larger than one individual.

To some extent, I still feel that way to this day and have never taken my full number of vacation days a year from SSPC. It is my own fault. It not only hurts me physically and mentally, but it hurts the folks who work here. They need a break from me as much as I need a break from the work.

Those of you that know the SSPC staff understand that we have a lot of folks who have worked here a long time. They know their jobs and do them well. The message that the staff receives when I am here all the time is that I don't trust them and I don't have faith in them, even though I do. If I can't get away for a period of time, I have done a poor job of training them.

We will not be at our jobs forever. We might leave for another job, retire, or for some other reason just move on. Getting away on a nice long vacation allows us to see if we, as leaders, have done our jobs of training, and that our subordinates can handle the decisions that need to be made to keep things running smoothly. Being absent also allows us to think of the bigger picture and examine where the business is going strategically.

Every day that I am in the office, I jog at lunchtime. It is amazing how this clears my mind and allows me to take a wider view of how things are going at SSPC. If I took a longer break, I might do a better job of conducting that wider focus of the organization that every leader needs to take. So take a break, take a vacation and see how your organization is really operating. It might surprise you.

SSPC Releases Guide 20 for Thick Film Concrete Floor Coatings

SSPC Committee C.7.1, chaired by Thomas J. Murphy of ATC Epoxy, recently issued SSPC Guide 20, Guide for Applying Thick Film Coatings and

Surfacings Over Concrete Floors. The Guide is a major revision and reorganization of the similarly titled SSPC-TU 10 Technology Update. The reorganization incorpo-

rates many of the elements formerly in the TU 10 appendices into the body of the Guide, removing unnecessary duplication of information.

Ault, Brown to Head SSPC 2015 EPAC

SSPC recently selected members for the Education Program Advisory Committee (EPAC) for SSPC 2015 featuring GreenCOAT, which will be held February 3-6, 2015, in Las Vegas, Nev.

J. Peter Ault of Elzly Technology Corporation was named Chairman of the EPAC. Ault has been actively involved in various aspects of corrosion control and materials engineering for over 20 years, and he has been a principal at Elzly since 2006. He is an active member of several technical societies, including SSPC, ASTM International, NACE International, ASNE, SNAME, and NSPE. He is also a registered Professional Engineer in New York and New Jersey, holds Protective Coatings Specialist certifications from both SSPC and NACE, and holds a B.S. degree in mechanical engineering and an MBA from Drexel University.

Charles Brown of Greenman-Pedersen, Inc. was selected as the EPAC Co-Chairman. Brown has over two decades of experience in the coatings industry, during which he has performed paint inspections, safety audits, and has taught courses nationally for SSPC. Brown was the Tutorial Program Chairman for the SSPC Conference in Houston, Texas, and is a past SSPC Chairman for the Painting Contractor Certification Program Advisory Committee. Through

J. Peter Ault

Charles Brown

GPI, he is currently providing services for the Maryland State Highway Administration as an Area Engineer for their Coatings Division.

Other members of the SSPC 2015 EPAC are:

- Earl Bowry, Jotun Paints, Inc.;
- Robert Cloutier, Bath Iron Works;
- Heather Gilmer, Tampa Tank & Florida Structural Steel;
- Bob Murphy, The Sherwin-Williams Company;
- Cyndi O'Malley, KTA-Tator, Inc.;
- Steven Reinstadtler, Bayer MaterialScience LLC;
- Mark Schultz, The Sherwin-Williams Company;
- David Tarjan, Halox;
- Ernst Toussaint, Trans Canada;
- Dwight Weldon, Weldon Laboratories, Inc.; and
- Joyce Wright, Newport News Shipbuilding.

For more information on the SSPC 2015 conference, visit sspc2015.org.

Although intended primarily for flooring and surfacing contractors, the Guide can also be used by specifiers who need a general introduction to flooring installation considerations and procedures.

Guide 20 is organized in the same way a flooring installation project would progress. It provides general guidance for contractors on the basics of performing a pre-bid evaluation of newly installed concrete substrates or conducting a condition survey for replacement or maintenance projects; considerations for selecting surfacings based on service environment; guidance for moisture evaluation, general surface preparation, and contaminant removal; and specific recommendations for preparation and successful installation of various generic types of flooring systems. A checklist to aid contractors in developing their work plans for specific projects has been added as an appendix.

SSPC Members can download the new standard for free at www.sspc.org/market-place/standards/technology-guides. Non-members can purchase the standard for \$25 via the same link. The current version is also available on the SSPC App.

PaintSquare Digital Exhibits Bring the Show to You

Missed some exhibitors on your busy rounds at the last conference? New "digital exhibits" can give you a closer look at some of those companies and their products.

For the first time, Technology Publishing Co. (publisher of *PaintSquare News* and the *Journal of Protective Coatings & Linings*) offered exhibitors at SSPC 2014 the opportunity to make video presentations that answer frequently asked questions about their companies, reveal information about new or upcoming product releases, and showcase their existing product lines.

These three to five minute videos will be posted in a sponsored area on paintsquare.com and on the SSPC 2014 Video Proceedings website on sspc.org. Videos are available from:

- MMLJ/Dustless Blasting;
- Novatek Corporation;
- FESI-BOND BLAST X1, by Stable Lead;
- Safety Lamp of Houston; and
- Safway.

SSPC 2014 featuring GreenCOAT took place Feb. 10–13 at Disney's Coronado Springs Resort and Convention Center in Orlando, Fla.

For more information, visit www.paintsquare.com/sspc videoproceedings.

JPCL

Editor's Note

In his article "Maximizing Water Tank Service Life Using a Design-Build Approach" (*JPCL* May 2014), Daniel J. Zienty references inspecting tank surfaces and appurtenances in accordance with AWWA D101 (AWWA Standard for Inspecting and Repairing Steel Water Tanks, Standpipes, Reservoirs, and Elevated Tanks, for Water Storage). *JPCL* recognizes that ANSI/AWWA D101-53 (R86) was withdrawn as a standard by AWWA in 1998 and that a task group is currently at work on a revision of the standard.

A representative of the AWWA standards engineering department acknowledges that the content of D101 remains in a current AWWA publication (in appendix C of AWWA Manual M42 on Steel Water-Storage Tanks, 2013), even though D101 is no longer a standard, and that application of information in the standard requires the evaluation and judgment of a qualified professional on a case-by-case basis.

Although intended primarily for flooring and surfacing contractors, the Guide can also be used by specifiers who need a general introduction to flooring installation considerations and procedures.

Guide 20 is organized in the same way a flooring installation project would progress. IOZ : OZ

What are the significant performance differences between an inorganic zinc primer (ethyl silicate) and an organic zinc primer (epoxy), given the same application and exposure conditions?

Dan Durus
Chimtitan

The drying time for ethyl silicate zinc-rich primers is much less than the drying time for epoxies. The temperature resistance for ethyl silicate is up to 400 C and can be up to 600 C if it is topcoated with aluminum silicone. Also, a zinc-rich ethyl silicate primer requires a minimum surface preparation of Sa 2 ½ (SSPC-SP 10, Near White Blast Cleaning).

David Lemke
Team Industries

Inorganic zincs (IOZ) normally have more zinc in direct contact with the substrate, whereas organic zincs (OZ) will have the zinc suspended throughout the film layer. As a result, the IOZ may offer a higher level of cathodic protection than OZ. As Dan mentioned, IOZ can withstand higher temperature service environments and UV protection over OZ. Some coating manufacturers will allow an SSPC-SP 6 (Commercial Blast Cleaning) surface cleanliness standard for the application of IOZ but will state that in severe service environments, a minimum of SSPC-SP 10 (Near White Blast Cleaning) will be required. OZ usually can be applied to a lesser degree of surface preparation. Another problem with IOZ is the moisture cure of the product. In a

heated shop in winter, where I live, the heat just sucks out the moisture, making the coating tough to cure out. We have a special room where we induce moisture to cure the IOZ. Then there is the added mist coat that normally doesn't need to be done on the OZ. The OZ dries much faster and is preferred in three-coat systems.

So, to me, the significant differences are that IOZ will offer more cathodic protection, UV resistance, and withstand much higher service temperatures. OZ can be used in situations where elevated surface preparation is not attainable, as long as heat is not a factor. A coat of urethane can be applied on most OZ for UV protection because heat is not a factor.

Willie Mandeno
Opus International Consultants Ltd.

There are no significant differences when correctly applied, topcoated with organic intermediate/finish coats, and exposed to normal atmospheric conditions. However, zinc silicate's significant difference is its superior performance under atmospheric exposure when applied without a topcoat because of its more durable and conductive binder, which is more resistant than OZ coatings to UV, heat, and abrasion.

Louis Vincent
L.D. "Lou" Vincent Ph.D. LLC

IOZ primers have the longest proven corrosion prevention, whereas the OZ primers are the most user-friendly to apply. The real problem lies in applicator training. Most applicators are trained using organic coatings—mostly organic topcoats. When faced with applying an inorganic primer, they use improper techniques because they were never trained to apply IOZ primers. Mud cracking is an applicator problem, not a coatings problem.

Derek Righinni
Certified Coating Inspection Ltd.

Both ethyl silicate and epoxy zinc-rich coatings may provide cathodic protection if loaded with sufficient zinc pigment so that the pigments are in contact with the substrate. Ethyl silicate is prone to mud cracking, but this is an application difference and not a performance difference. Organic binders are subject to the same frailties as all organic beings, including extreme temperatures, aging, and UV; whereas, inorganic binders are far more resistant to our organic frailties and perform much better in these conditions.

Neelakandan S.
RPM Saudi Arabia LLC

Notable differences favoring epoxy zinc-rich primers include hardness, excellent bond strength, and greater adhesion when compared with inorganic zinc-rich counterparts that are known for mud cracking and poor scratch hardness resistance.

SSPC PROTECTIVE COATINGS SPECIALIST

Q & A with VAUGHN O'DEA

by Charles Lange, JPCL

Vaughn O'Dea is the director of sales for water/wastewater at Tnemec Company, Inc. In this position, Vaughn works with water and wastewater engineers and facility owners to select the appropriate high-performance protective coating and lining technologies designed to withstand these environments. "One day I might be with our local sales representatives giving formal presentations, and the next day I'm putting on a hard hat and training contractors in the application of our products," says Vaughn. "Whether it's in an engineer's office assisting with a project specification, or at the bottom of a lift station getting dirty, it's never a dull moment."

With almost 15 years of experience in the protective coatings industry, Vaughn is an SSPC PCS; a NACE-certified Corrosion Technician; an active participant on both SSPC and NACE technical committees; and a member of the American Water Works Association (AWWA), the Water Environment Federation (WEF), the American Concrete Institute (ACI), the International Concrete Repair Institute (ICRI), and ASTM International. A graduate of the University of Kansas, Vaughn is also a contributing editor of the JPCL and was named a JPCL Top Thinker in 2012.

JPCL: How did you get your start in the protective coatings industry?

VO: I went to work for Black & Veatch's water division as a construction manager fresh out of college. On my first assignment I encountered a coating failure. My colleagues were unable to offer an explanation beyond "poor surface preparation." The fact that surface preparation could cause this type of failure was unsettling to me, so I kept asking. I wanted to know specifically how to prepare surfaces correctly in order to prevent this on future projects. My persistence introduced me to the SSPC Painting Manual, which I suspect was one of the first editions based on the tattered condition and significantly fewer pages compared to a current edition.

Perhaps the Socratic paradox resonated, "The more you learn, the more you realize how little you know." I read every JPCL issue incessantly from front to back. Next thing I realized, my employer was sending me to NACE's CIP and Corrosion courses and before long I became the Protective Coatings Specialist for their water division.

JPCL: How vital is the role that coatings play in maintaining water and wastewater infrastructure in this country going forward into the future?

VO: The population in the U.S. continues to increase, imposing demands on municipal utilities that exceed capacities, in many cases. Compounding this issue is the well-known fact that much of our drinking water infrastructure, as well as wastewater collection and treatment infrastructure, is nearing the end of its useful life. Failing infrastructure is not only an inconvenience it financially impacts all of us in the U.S. Investment in water and wastewater is not able to keep pace with the current and future need, which has given birth to asset management and sustainability concepts that can extend the asset life. High-performance protective coatings and linings will certainly play a significant role in protecting new and rehabilitating existing infrastructure, especially technologies that can demonstrate increased protection.

JPCL: What are some of the main challenges you face in your day-to-day work?

VO: As we are promoting and utilizing new higher-solids coatings, the surface prep and application parameters are constantly changing. It can be challenging to keep up with. Oftentimes, we as coatings professionals need to overcome our past experiences and "retrain" ourselves to these newer, more sophisticated technologies. This is an example where a young person can really make a difference. Sometimes, it's almost preferable to have someone with less experience working on a project, because that person is trainable and won't be as influenced by past experiences.

SSPC PROTECTIVE COATINGS SPECIALIST

JPCL: What's the biggest change you've seen in the industry over the course of your career?

VO: I think there has been much more emphasis on preparing—and repairing—both new and existing concrete surfaces. Knowledge about concrete as a substrate has increased, and more advanced technologies are available to solve some of the problems concrete can pose. I'd like to think that, through my work, I have shepherded some of these changes.

JPCL: What are some changes you'd like to see in the coatings industry, whether it regards standards, public policy, work practices, or just general attitudes throughout industry professionals?

VO: I'd like to see us continue to improve our concrete surface prep and application standards. Concrete is still, in many ways, a relatively unknown substrate, so it's important that we continue to research and advance our understanding of it.

I'd also like to see the industry embrace the concept of sustainability. In this country, as opposed to others around the world, we often accept the lowest bid for a job, without considering who will offer the longest service life. It's important to focus on life cycle cost analysis, not just which contractor can perform the job the cheapest. This thinking should factor into product selection, as well.

JPCL: Is there a project or paper that you worked on in the past that was particularly memorable? What made it memorable for you?

VO: A number of noteworthy projects come to mind, but one particular research project that is special is one we affectionately refer to as the "ICRI Mortar Study," which involved significant resources and coordination from our company, including our research and development, product support, and technical support departments. Our findings were presented at several industry conferences and in trade journals. The results of this study revealed that most cementitious repair mortars (epoxy cements being the only exception) form a laitance layer that must be removed to achieve optimum adhesion of the high-performance topcoat. These findings helped shift the paradigm on how cementitious repair mortars are treated when it comes to topcoating for severe service and containment environments.

JPCL: What advice would you give a young person looking to get into the coatings industry today?

VO: The coatings industry is ever evolving, so there's a

lot of opportunity for young, enthusiastic individuals to really shape the direction of the industry, whether it's on the research and development end, or through contracting and engineering. Coatings practitioners can advance the industry technically by simply acknowledging and tackling challenges, and then documenting how they are resolved. To this day, I look at myself as somewhat of a newcomer. I wasn't experienced at first; I just got my start, tackled the problems I saw, and documented what I found. These kinds of results can really resonate throughout the industry.

JPCL: What has been the highlight or proudest moment of your career thus far?

VO: I recently played a modest role in seeing that the Severe Wastewater Analysis Testing Apparatus, also known as S.W.A.T., became an ASTM standard. This was a milestone for our industry's ability to demonstrate the suitability and sustainability of protective linings for use in the wastewater sector using current practices and techniques indicative of today's sewer conditions. As an industry, we have moved past the "acid contact" testing, historically used to evaluate a protective lining for wastewater exposures, to now testing the sewer gas permeation resistance.

JPCL: What are your interests outside of work? How do you like to spend your free time?

VO: I enjoy hunting deer, coyotes, wild turkey, and various upland and migratory birds. I also enjoy the nonstop entertainment provided by my two young daughters, Grace, 7, and Betsy, 5, and the company of my wonderful bride. Occasionally, I get a round of golf in, too!

O'Dea spends some of his free time hunting several different types of animals, including wild turkey and other upland and migratory birds.

Applicator Training Bulletin

It is essential to follow proper equipment setup and maintenance procedures during air spray coating operations. All photos and figures courtesy of Finishing Brands, Inc. (DeVilbiss, Ransburg, BGK, and Binks).

Setting Up, Operating, and Maintaining Air Spray Equipment

First, why spray? Use of spray technology to apply your coating brings advantages of speed; uniformity of application for quality control and lower coating costs; and reduced labor expenses when compared with using a brush or roller, especially on irregular surfaces and intricate shapes.

The two most common methods of paint spray application are air atomized spray and airless spray. Air atomized spray uses compressed air to atomize, or transform, a coating into very fine particles or droplets as it exits the spray gun. In airless spray, a pump pressurizes the coating at a high level and forces it through a small elliptical orifice, or opening, as it exits the spray gun, causing the paint to atomize hydraulically.

This Applicator Training Bulletin describes

the proper methods of setting up, operating, and maintaining air spray equipment, specifically conventional and high volume low pressure (HVLP) technologies. Low volume medium pressure (LVMP) technology is also addressed.

Setting Up Air Spray Operations

Figure 1 shows one configuration of an air spray equipment system. Components needed to apply coatings by air spray are:

- an air compressor;
- a compressed air filter;
- an air supply hose from compressor to paint tank or pump;
- air regulators with gauges;
- a container for the coating (pressure-feed tank or pot, gravity/siphon cup, or paint pump);
- a paint agitator, if necessary;

- a fluid hose to supply coating to the spray gun (if using a pressurized gun);
- an air hose to supply atomizing air to the spray gun; and
- an air spray paint gun.

The most important element in air spray application is the person operating the gun. The operator is responsible for applying the coating, using a technique best suited to the job, and keeping equipment in good working order.

Air Compressor

The air compressor needs to supply clean, dry air of sufficient volume and pressure for all of the components in the air spray system. Typically, each full-production spray gun requires 15–20 CFM of compressed air, and each air-driven agitator requires 10–15 CFM of compressed air. Air pressure at the air compressor of 90–100 psi is recommended. Air compressors are usually equipped with an air receiver tank, drain, and oil separator.

Compressed Air Filter

An air filter will be needed between the compressor and the pot, especially on humid days. It is important to periodically drain moisture from the air filtration unit. If the unit is equipped with an automatic drain, ensure that a preventative maintenance program is in place.

Air Supply Hose

Check the air hose and fittings from the air compressor to the paint tank or pump to make sure they are in good condition and free of leaks. The inside diameter (ID) of the air hose needed is based on the length of the hose and the number of guns and air agitators used. Typically, for a one-gun setup, a 3/8-inch ID air hose up to 50 feet long is sufficient.

Coating Containers

Siphon or gravity gun setups use a cup attached to the gun to deliver the coating.

For bigger jobs that require more paint, using a pressure-feed paint tank, also called a pressure pot, is an economical method of supplying coating to the spray gun. Flow is positive and uniform as paint is forced out of the tank by applying compressed air to the coating. Increasing or reducing the tank air pressure increases or decreases the flow of paint from the tank. Maximum tank working pressures can vary from 60–110 psi. Read the rating on a tank before using it.

The tank is a metal container with a removable, clamp-on lid that has a sealing gasket. The lid forms an airtight seal when securely clamped to the tank shell. Sizes of tanks vary from two quarts to twenty gallons; two and five gallon tanks are the most common.

Other features of the tank are a fluid-riser tube and an outlet manifold (or a bottom outlet used with heavy or highly-filled paints), a fluid outlet valve, a safety relief valve on the tank lid, a tank air vent valve, and tank air pressure regulator(s) with gauge(s). Consider accessories such as an air-driven paint agitator to easily mix or keep paint in suspension. Tank liners also make cleanup easier.

A paint pump can be used in place of a pressure pot. The paint pump pressurizes paint and forces it from a source container

Editor's Note: This Applicator Training Bulletin is an update of an original article on conventional air equipment, written by Herb Chilman and Jerry Gonser of Spray-Quip, Inc. The article originally appeared in the June 1989 issue of the JPCL and was updated for this issue by Steve Stalker for Finishing Brands, Inc. (DeVilbiss, Ransburg, BGK, and Binks).

to the gun. As with a tank, the paint pressure is controlled by the pump air regulator. The paint pump has several advantages over a pressure tank. The pump normally draws the paint from the original paint container, can operate at higher pressures, is lighter in weight, and is easier to clean than the tank. However, a pump is more complex than a tank and does not deliver paint as uniformly as a tank.

Hoses

The fluid and air hoses that supply paint and atomizing air from the tank or pump to the spray gun should be serviceable, clean, and of the proper size and inside wall construction. The normal sizes are $\frac{5}{16}$ -inch ID for paint and $\frac{3}{8}$ -inch ID for air. When paint is viscous (thick, for example), highly filled, or pressure-sensitive, or when the hose run is over 50 feet long, a $\frac{3}{8}$ -inch ID paint hose may be recommended. Follow the paint manufacturer's instructions on proper hose size.

The standard paint hose liner is nylon; the standard air hose liner is a synthetic rubber.

Spray Gun

The operation of an air atomized spray gun involves atomizing a stream of fluid with a stream of compressed air. The air-to-paint balance is controlled by the viscosity (thinness or thickness) of the paint and the air pressure put on the paint in relation to the volume and pressure of atomizing air. The spray gun has a fan control knob for adjusting fan width within the limits of the air cap. Figure 2 shows the various parts of a typical air spray gun.

In recent years, low volume medium pressure (LVMP) guns have been developed. LVMP has the atomization benefits of conventional air spray and the efficiency of HVLP. If you are not required by a regulatory agency to use HVLP, LVMP is highly recommended.

If you are not using a spray gun designed in the last ten years, the air reduction savings for modern spray guns will typically be greater than the cost of purchasing new spray guns.

Start-Up Procedure and Operation

Begin setting up the equipment by connecting the air hose and the paint hose to the spray gun and pressure tank. Then, turn the tank and gun air regulator handles counter-clockwise so there will be zero pressure when the main air supply is connected to the tank. Next, pull the ring on the safety pressure relief valve on the tank, to make sure it operates freely. Close the main air supply valve on the tank, and tighten the tank lid clamps. You are now ready to connect the main air supply hose to the tank.

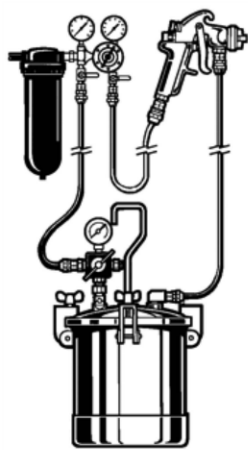

Fig. 1: Typical air spray pressurized system (single regulated) configuration, using a pressure-feed paint tank

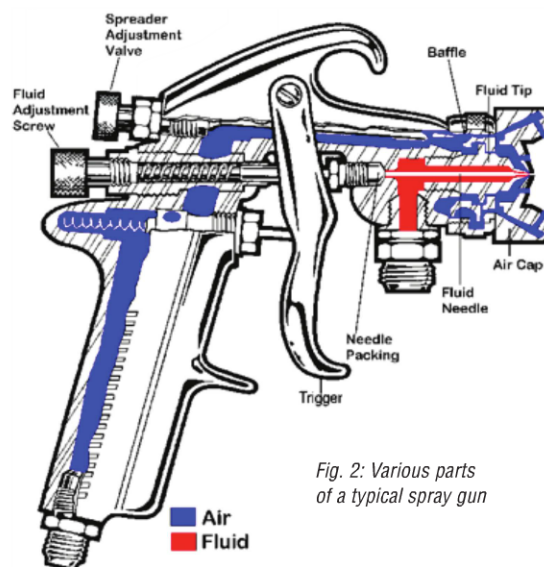

Fig. 2: Various parts of a typical spray gun

Applicator Training Bulletin

Once the main air supply hose is securely connected to the pressure tank, slowly open the main air supply valve on the tank. Look at the regulator air gauge. If it shows pressure, turn the handle counter-clockwise to reduce pressures to zero.

Prior to loading the paint into the tank, check for proper operation of the tank and fittings. Adjust the tank regulator to 10 psi to pressurize the tank. Look and listen for leaks around the tank lid and fittings on the lid, as well as leaks at paint hose connections to the tank and the gun.

Prior to connecting the gun to fluid and air, adjust the fluid adjustment screw until the trigger can be fully pulled toward the rear of the gun. While holding the trigger to its maximum travel, turn the fluid adjustment knob clockwise until it stops.

Adjust the air regulator to the spray gun to 20 psi. Check for air leaks at hose and gun connections.

Prepare the coating (by mixing, thinning, etc.) to the correct spraying viscosity suggested by the manufacturer. Remember that spraying viscosity can vary considerably with the temperature of the paint.

Maintaining a consistent coating temperature will help ensure the consistent atomization of the coating. Load the prepared paint into the pressure tank. Clamp the lid tight, turn the air regulator handles counter-clockwise so that zero pressure shows when the main air supply is on, and then turn on the main air supply.

Hold the spray gun and point it toward a grounded waste container. Trigger the spray gun fully. No air or paint should be flowing from the gun. While holding the gun with the trigger fully depressed, you should then fill the paint hose with paint by increasing the tank pressure regulator to 5 psi for thin materials or 10 psi for thick materials. Remember, the hose is full of air, so keep the gun open to remove the air. Let the stream of paint continue to flow from the gun until all air

bubbles are pushed out and a solid stream is achieved.

Setting Pressures on a Pressurized System

- Step 1: Using control knob on fluid regulator, set fluid pressure at 5–10 psi.
- Step 2: Using control knob on air regulator, set air atomization pressure at 30–35 psi.
- Step 3: Spray a test pattern (fast pass) on a piece of paper, cardboard, or wood. From that test pattern, determine if the particle size is small enough and uniform throughout the pattern to achieve the required finish quality. If particle size is too large or is giving too much texture in the finish, turn the atomization pressure up in 3–5 psi increments until particle size and texture of finish is acceptable.
- Step 4: Spray a part with these settings. If you are not able to keep up with the production rate required or if the finish is starved for material, increase the fluid pressure in 2–4 psi increments using the fluid regulator control knob (or use a larger capacity fluid tip) until required wet coverage is accomplished.
- Step 5: Remember, as you turn up the fluid pressure, the particle size will increase. Once the coverage required is obtained, it will be necessary to re-adjust the atomization pressure in 3–5 psi increments, as explained in Step 3, to insure required particle size and finish texture is achieved.
- Step 6: If using HVLP, use an "Air Cap Test Kit" to verify that the air cap pressure is not above 10 psi, if required by a regulatory agency.

Proper setup utilizes no more fluid and air pressure than is needed to produce the required quality and a flow rate that will meet production requirements.

Setting Pressures on a Gravity or Suction Feed System

- Step 1: Spray a horizontal test pattern (air cap horns in a vertical position). Hold the

trigger open until the paint begins to run.

There should be even distribution of the paint across the full width of the pattern. The fan control knob is normally adjusted fully counter-clockwise. If the distribution is not even but is symmetrical, a different fluid tip may help. If the pattern is not symmetrical, there is a problem with either the air cap or the fluid tip/needle that must be corrected.

- Step 2: If the pattern produced by the above test appears normal, rotate the air cap back to a normal spraying position and begin spraying. (Check the service literature for typical pattern size for the cap you are using).
- Step 3: With the fluid adjusting screw properly set, and the air pressure set at approximately 30 psi, make a few test passes with the gun on some clean paper. If there are variations in particle size specks and/or large globs, the paint is not atomizing properly.
- Step 4: If the paint is not atomizing properly, increase the air pressure slightly and make another test pass. Continue this sequence until the paint particle size is uniform.
- Step 5: If the pattern seems starved for material, and the fluid adjusting screw is set to maximum travel, the atomization air pressure may be too high, or the material may be too heavy. Recheck the viscosity or reduce the air pressure.
- Step 6: If the material is spraying too heavily and sagging, reduce the material flow by turning the fluid adjusting screw (clockwise).

The proper spray technique is to hold the gun perpendicular to the surface to be sprayed at a distance of approximately 12 inches. Swinging the gun in an arc will greatly reduce the quality of the painted surface.

Maintenance

Following a few maintenance procedures can help ensure the quality of your work.

- During start-up and operation, periodically check air gauges and pressure relief valves.
- Drain air filters periodically. Lubricate and

adjust the spray gun paint needle packing daily.

- Because the gun air cap and fluid nozzle determine the quality of your spray pattern, you should clean the air cap and fluid nozzle as needed, following the manufacturer's directions.
- Use only the proper wrenches and cleaning brushes. Do not use items such as channel locks or steel brushes, which will damage the cap or nozzle.

Cleanup

To prepare for the cleanup procedure, turn off the tank air pressure, vent the tank, loosen the air cap ring of the spray gun by turning it three times, hold a cloth over the air cap, and pull the trigger to force paint back into the tank. Remove the tank lid from the tank, and pour paint from the tank back into the original container.

To clean the equipment, first pour a small amount of cleanup solvent into the tank, and wash the sides of the tank and the paint riser tube, agitator, etc. Then, install the tank lid, pressurize the tank, shut off the atomizing air to the gun, remove the air cap, and trigger the gun. Be sure to catch the cleanup solvent in a grounded waste container. Repeat the operation until the tank, hose, and gun are clean. During the final operation, blow the system dry using compressed air. Next, remove the spray gun, wipe it clean, and lubricate it. Do not put the gun in a bucket of solvent to clean it; the solvent will attack the packings, causing the gun to leak. Remove the air and fluid hoses and roll them up. Remove the tank lid, wipe the tank and the lid clean, and reassemble them. Once these parts are reassembled, turn off the air at the compressor, relieve the air pressure, and

remove and roll up the air supply hose. All components should then be stored in a secure area.

Conclusion

The success of any spray job depends on the skill of the operator and on his or her understanding of the equipment with which he or she is working. To ensure a successful spray application, remember these key points.

- Follow paint and equipment manufacturers' recommendations.
- Use properly sized equipment.
- Follow the spraying, maintenance, cleanup, and safety procedures described above.
- Use common sense.

WHAT YOU DON'T KNOW CAN HURT YOU

Fight Corrosion Under Insulation with Versiline CUI 56990

- **Reduced risk of Corrosion Under Insulation**
- **Better heat resistance performance**
- **Lower maintenance costs**
- **Reliable and safe process equipment**

Versiline CUI ensures a safe, reliable and cost effective process environment, with less risk of unexpected shutdowns and lower maintenance costs. Versiline CUI offers a unique combination of CUI and heat resistance that delivers superior performance and excellent crack resistant and adhesive properties making it extremely durable. Even when using standard equipment, it is quick, easy and straightforward to apply Versiline CUI.

Differential Scanning Calorimetry

By Dwight G. Weldon, Weldon Laboratories, Inc.

As readers of *JPCL* likely know, coating failures are, unfortunately, a part of our industry. While the types and diversity of failures seem to be almost limitless, there are a limited number of laboratory techniques that are typically used to help solve them. This first article in a new series called “Tools of the Trade” will explore one such technique—differential scanning calorimetry (DSC). DSC is a very useful technique if there is the possibility that a failure is due to improper curing of the coating, or if the coating is not suitable for the temperatures at which it has been placed in service.

Calorimetry, as the name implies, deals with heat. Most anyone who ever took a freshman chemistry class in college probably used the simplest of calorimeters—a styrofoam cup complete with a lid and a thermometer. A very simple experiment may have consisted of adding a known amount of water to the container, adding measured amounts of a couple of chemicals that could react with one another (perhaps powdered zinc and hydrochloric acid), giving the whole thing a swirl or two, and then seeing how hot the water got. Knowing that it takes one calorie of energy to raise one gram of water 1 C (the specific heat capacity of water), one could calculate the heat of the reaction between the zinc and the acid.

A differential scanning calorimeter costs much more than a styrofoam cup and a thermometer, but it can provide a great deal more information. It is basically a very expensive furnace, which can be programmed to

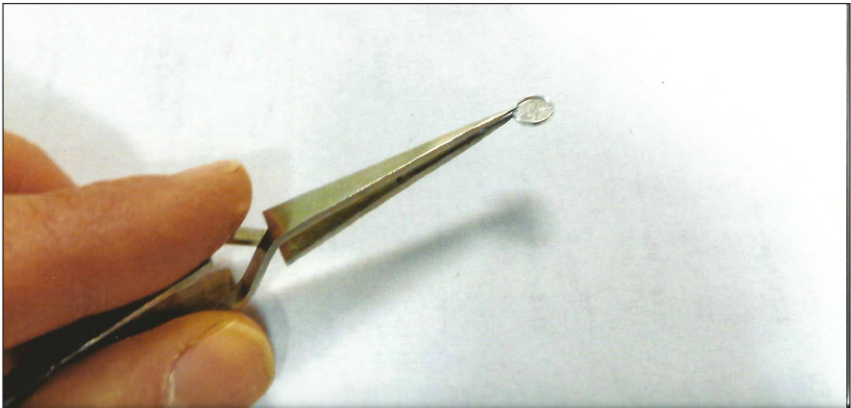

Fig. 1: Sealed aluminum sample pan containing a paint chip for DSC analysis. All figures courtesy of Weldon Laboratories, Inc.

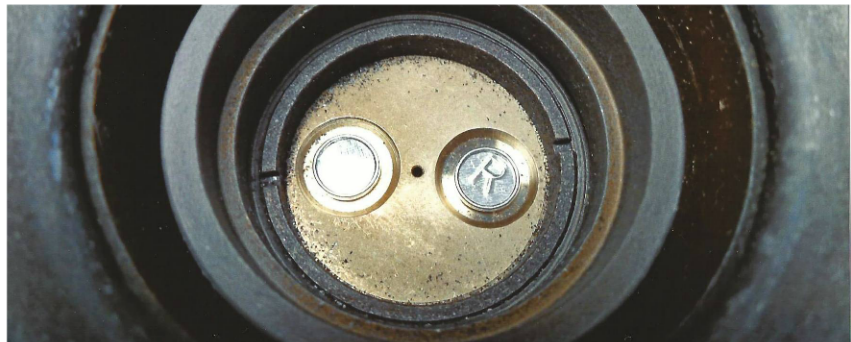

Fig. 2: The furnace chamber of a DSC showing the sample and reference pans sitting on their individual platforms

heat up (or cool down) at very precise rates. In the world of failure analysis of paints and coatings, the sample is usually a paint chip, sealed inside a small aluminum pan (Fig. 1), and the reference is simply an empty aluminum pan. Inside the instrument are two platforms (Fig. 2)—one for the sample and one for the reference. There are thermocouples, or some other means of measuring temperature, attached to the underside of the platforms. The purpose of the experiment is to detect “thermal events,” such as melting

points, heats of reaction, or glass transitions, which may have some bearing on the mechanism of the coating failure.

Once everything is in place, the experiment is started. A typical experiment might involve raising the temperature inside the furnace from, say, 0 C to 150 C at 10 C/minute. The data collected by the instrument is essentially a graph of heat flow versus temperature. If nothing were to happen with the sample over the temperature range of the experiment, the output would

essentially be a straight line. However, if a thermal event occurs, there will be a deviation from this straight line. The shape or direction of this deviation depends on the

nature of the event.

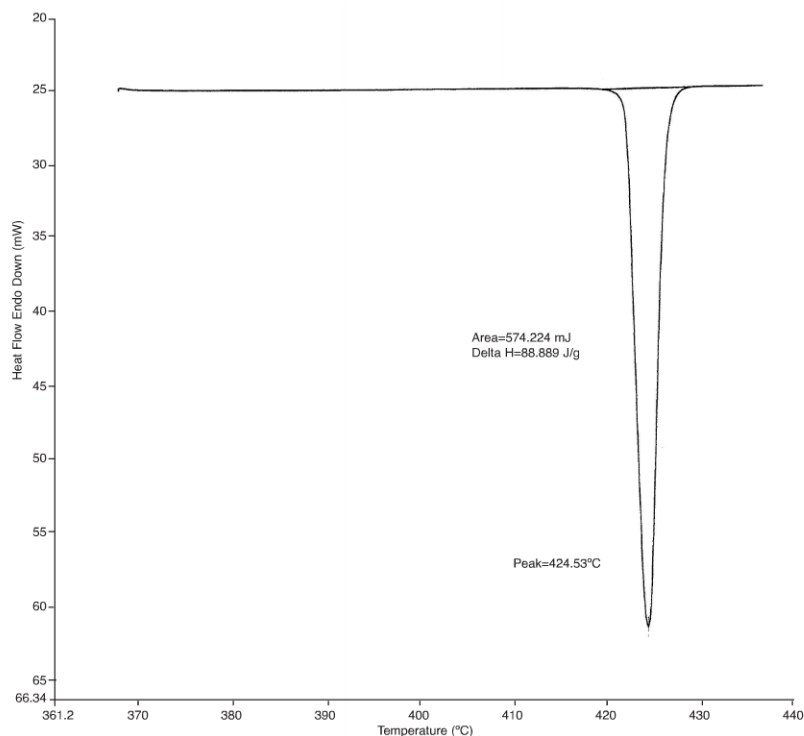

For instance, for something in the sample to melt, it would require energy. An event or reaction which requires energy is an

endothermic event. Because some of the energy being “pumped into” the sample is being used to melt it, there is less “leftover energy” available to heat it up. As a consequence, the temperature of the sample pan would lag, briefly, behind the temperature of the reference pan (where all of the supplied energy is being used to heat it up), and a peak would show up in the scan. Often, the instrument is set so that an endothermic peak points down (Fig. 3). In contrast, if a chemical reaction were to begin during the heating of the paint chip, this is an exothermic event which liberates heat, and a peak would show up pointing in the opposite direction. It is not uncommon for exothermic peaks to be broad, spanning several tens of degrees.

While melting points are rarely observed in failure analysis, the ASTM method for determining the amount of metallic zinc in a zinc-rich primer (ASTM D6580) is based on measuring the amount of energy required to melt the zinc. Indeed, Figure 3 shows the heating curve of a zinc-rich primer, with the melting of the zinc occurring near 420 C.

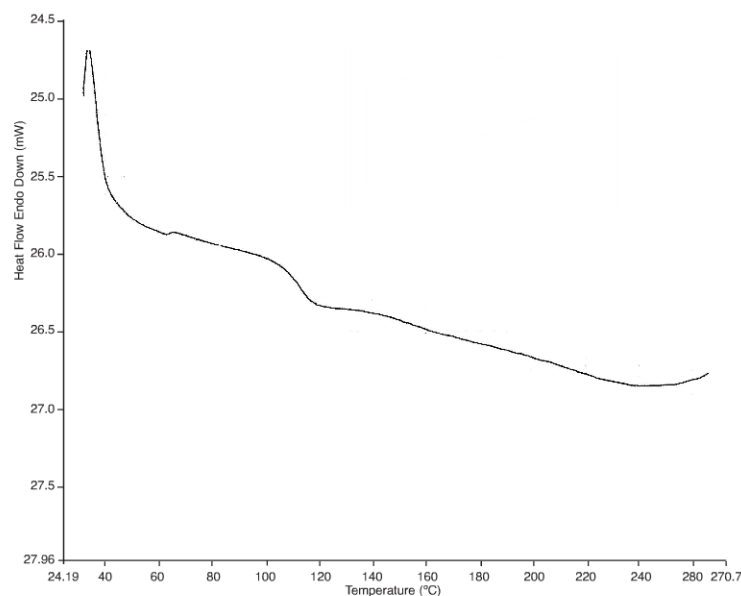

It is fairly common to encounter exotherms in failure analysis, especially with powder coatings and two-component coatings such as epoxies. They are usually due to the reaction between residual, uncured coating components (such as the reaction between an epoxy resin and an amine curing agent). An exotherm is often an indication that the coating is not fully cured, which is a very good thing to know when doing a failure analysis. With a powder coating, it often means that the coating was not baked at the right time and/or temperature. With an ambient cured coating, it might be an indication that something interfered with the curing mechanism. In any event, it gives a clue to what may have caused the failure.

Another very important reason to do a DSC experiment is to determine the coating's glass transition temperature (Tg). A very useful definition of the Tg is the

1) Heat from 370.00°C to 400.00°C at 10.00°C/min

Fig. 3: A DSC scan of an inorganic zinc-rich primer, showing the downward pointing endothermic peak due to the melting of the metallic zinc pigment

1) Heat from 35.00°C to 270.00°C at 15.00°C/min

Fig. 4: A DSC scan of a cured powder coating, showing the glass transition near 110 C

temperature below which a polymer (or coating) is in a glassy, brittle state, and above which it is in a flexible or rubbery state. The Tg does not show up in the heating curve as a peak, but rather as a relatively sudden change in the position of the baseline, in the endothermic direction (Fig. 4).

There are some important reasons to know the sample's Tg. The first reason is that, for thermoset coatings such as epoxies, urethanes, melamine crosslinked polyesters, and others, the Tg is proportional to the coating's degree of cure. So, if a properly cured or baked control sample has a Tg of, say, 53 C, and the failing sample has a Tg of only 42 C, the failing sample is undercured.

There are reasons why a coating manufacturer lists a particular mix ratio for a urethane or an epoxy, or why they require a certain bake time and temperature for a phenolic lining. Presumably, the coatings have their optimum properties at these mix ratios or bake conditions. An undercured coating will have poorer solvent resistance, and less chemical resistance in general, than a properly cured coating. These are extremely important considerations for coatings used to line chemical process vessels or tanker cars used to ship chemicals or foodstuffs. An undercured coating might even have less resistance to normal outdoor weathering, resulting in premature fading or loss of gloss.

As discussed above, the presence of an exotherm in the DSC scan is often an indication of lack of cure. However, there are scenarios where a sample might be undercured, but exhibit no exotherm. For instance, if only half the amount of amine curing agent were added to an epoxy, the amine would fully react with the excess epoxy, and there would be no subsequent exotherm in the DSC scan. However, the Tg would still be lower than it should be.

It should be pointed out that while DSC is an excellent tool for investigating lack of cure in a baked coating, it is somewhat

more difficult to apply the technique to ambient cured coatings. This has nothing to do with any deficiency in the technique itself, but rather to the difficulty of establishing what the "correct" Tg for the control sample should be. Many ambient cure thermoset coatings will continue to cure for a long time after they have been applied. Furthermore, a coating applied in a warm part of the country will cure faster than one applied in a cooler region. So, is the "correct" Tg the one obtained by applying the coating in the laboratory at 70 F and waiting one week before running it? Or should we wait two weeks? Or two months? DSC can still provide useful information on ambient cured coatings, but it is not always as straightforward as one would wish.

A second reason why it might be important to know the coating's Tg in the context of a paint failure is that coatings are considerably more permeable above their Tg. If temperatures exceed the Tg, there will be a sudden increase in the free volume of the sample (essentially, the "extra" volume not physically occupied by resin or pigment). This is a consequence of the polymer chains which make up the coating having more mobility above the glass transition temperature. The ability of these chains to move more freely tends to make the coating more "open," less dense, and hence more permeable. Generally speaking, one would not want to use a coating as a lining for a tank or chemical process vessel if the service conditions were above the coating's Tg, as more rapid permeation of the lining (and possibly premature failure) could result.

Ironically perhaps, there are also paint failures that happen because a coating is in service below its Tg. (What's a person to do? It's either too hot or too cold!) Remember, below the Tg the coating is in a brittle, glassy state. This is not always a good thing, since brittle, glassy coatings tend to crack when flexed or impacted. So, if the object being painted is expected to flex in

the wind, or be subjected to impact damage, it would be a good idea to use a coating which has a Tg close to or slightly below the expected service temperature. Likewise, if a coating has an appropriate Tg for the expected service, over-baking or over-catalyzing it can result in an elevated Tg, hence making the coating overly brittle and susceptible to cracking. DSC is a useful tool for investigating such problems.

DSC might also play a role in solving an aesthetic failure, such as excessive dirt pick-up. Paints retain dirt largely for two reasons: the surface of the paint is rough and full of tiny depressions or crevices, or the paint is too soft. Softness is a function of the glass transition temperature which, of course, can be measured by DSC.

DSC, like other techniques to be discussed in this series, has both strengths and weaknesses. It can provide certain pieces of information, but may or may not provide all that is needed to solve a coating failure. Part of the expertise of the investigator, or of anyone skilled in a particular trade, is knowing what tool to use for what job.

About the Author

Dwight Weldon is the president of Weldon

Laboratories, Inc., a company that specializes in

both routine testing and failure analysis of paints and coatings. Weldon has over 30 years of experience in the coatings industry, has performed thousands of paint failure investigations, and is the author of the book "Failure Analysis of Paints and Coatings," published by John Wiley & Sons. He has presented numerous lectures and workshops on failure analysis, and is a member of ASTM, SSPC, the American Chemical Society, and the Pittsburgh Society for Coatings Technology. He has a B.S. degree in chemistry from the University of Michigan and an M.S. degree in analytical chemistry from Michigan Technological University.

Field Application of Foul-Release Coating

By Sang-Ki Chi, Seung Hyun Kim,
and Byong Wan Kim
Institute of Industrial Technology,
Samsung Heavy
Industries Co., Ltd.

co-friendly technologies are currently on the rise in most marine and offshore industries. Ship owners, shipbuilders, and paint manufacturers are engaged in the reduction of VOCs and CO₂ emissions. Aside from decreasing environmental impact, low-friction hull coatings in particular are becoming popular with ship owners as an effective method of operational cost reduction. Many ship owners prefer to use silicone foul-release coating (FRC); however, this material requires more care with application than that of conventional self-polishing copolymer anti-fouling coating (SPC A/F). Consequently, shipbuilders are concerned with FRC application not only during construction, but also after delivery.

This article describes a study conducted during which the authors investigated several potential defects of field-applied FRC, and made suggestions about how to avoid them.

Normally FRC is applied as shown in Figure 1. FRC can be applied at the block painting stage or during a redocking stage.

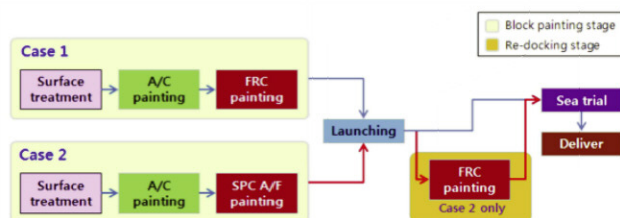

Fig. 1: Application flow chart showing process components of surface treatment, anti-corrosive coating application and FRC application in both block and redocking stages. All figures courtesy of the authors.

Considerations During Application

Spray Dust

Compared to conventional coatings, applying silicone-based, anti-fouling coatings by airless spray can produce a large amount of spray dust, which can easily lead to a surface contamination issue. This problem occurs even when FRC is applied under protection nets installed around the vessel from top to bottom. Spray dust can also

Fig. 2: Installation of the protection net

travel around the building dock contaminating other vessels under construction. In order to remove the overspray dust, a method such as high-pressure water jetting should be used. The builder should reinforce protection methods such as employing containment and broadening the protection area. Figure 2 shows the installed protection net.

Ventilation

When FRC is applied at the dry dock, a protective system should be installed (as above), which means that these areas become enclosed spaces, which presents a risk of explosion caused by solvent saturation. It therefore becomes necessary for the builder to analyze the flow path of air and arrange for the use of proper ventilation equipment.

Fluid analysis of solvents suggested that to provide proper ventilation and keep exposure limits at acceptable levels, the optimum arrangement of fans can be calculated by the size and geometry of both the dock and the ship, and the part or parts being sprayed.

Seeding

Flocculation of solid material by a physical or a chemical reaction can result in seeding, which is the formation of large particles referred to as gels. This event does not always occur, but it is seen in some batches of paint after mixing, and can also clog the spray tip. Repeatability tests were carried out with each coating type by sampling several batches of material and observing the reaction time with air. Silicone coatings are very sensitive to atmospheric moisture, even under winter conditions. Reaction test results of each component to moisture (base, curing agent, and catalyst)

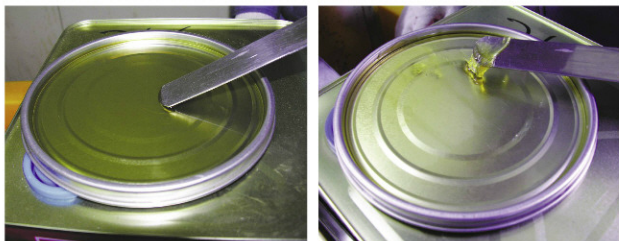

Fig. 3: Gelling of catalyst initially (left) and after five minutes (right)

noted that only the catalyst (Part C) reacted with air after five minutes of exposure (Fig. 3). The catalyst changed into a gel state by itself.

As a result of this test, it is recommended that FRC should be carefully handled by mixing each component just before application. Catalysts should not be opened earlier than 10 minutes before mixing to prevent reaction with moisture.

Pin Holes

Even with effective surface treatment, pin holes may still be detected and may be due to one of the following causes. If the vessel has been immersed in the sea water for more than six months, especially in the summer season, holes can form from biocide leaching out from the film and can cause a capillary phenomenon.

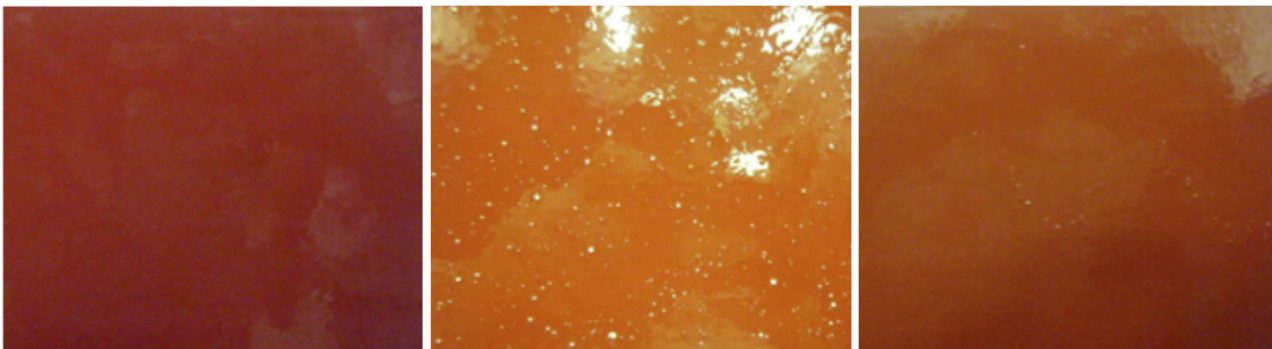

Fig. 4: Specimens of cissing simulation test: dry (left), water spray (center), and condensation (right).

As mentioned previously, FRC can be applied during the redocking stage before sea trials. In this case, a conventional anti-fouling coating is applied at the block-painting stage to prevent excessive sea organisms from attaching to the hull during mooring at the quay side. Therefore, FRC should be applied only after high-pressure washing and power-tool cleaning to remove sea organisms at the dock.

Secondly, after surface preparation, contamination such as the product of a reaction between copper oxide and sea water can remain on the film surface. Thus, a mist coat (or sealer coat) is recommended after fresh water washing to remove surface contamination.

Cissing

This defect is known as a kind of wetting problem caused by oil or other contaminants on the surface. Cissing can occur when the surface is contaminated by low surface tension material, but this condition was found on the FRC finish coat in the late afternoon and was presumed to be caused by moisture condensation on the surface. Accordingly, reproducibility tests were carried out to simulate the actual conditions.

Moisture condensation, water spray and dry specimens were prepared. An FRC finish was then applied to every specimen. After the test, the wetted panels caused cissing. The dry one did not (Fig. 4). This means that the surface condition is very important, because FRC may easily create this defect by its hydrophobic property. The coating inspector and manager in charge of the painting project should carefully check the surface condition before FRC application.

Table 1: Coating Schemes of Test Specimens

No. of coat	SPC A/F	FRC
1st	Epoxy Anti-Corrosive 150 μm	Epoxy Anti-Corrosive 150 μm
2nd	Epoxy Anti-Corrosive 150 μm	Epoxy Anti-Corrosive 150 μm
3rd	Epoxy Tie Coat 100 μm	Silicone Tie Coat 100 μm
4th	SPC A/F 150 μm	Silicone Finish Coat 150 μm

Table 2: Friction Resistance Test Results

Paint	Block Type	Friction Value (kg)		Remarks
		Min.	Max.	
SPC A/F	A	N/A	N/A	Laminating film pushed out
	B	305	361	Damaged
FRC	A	34	58	No damage
	B	37	60	Damaged

After Application

Mechanical Damage

Silicone FRC has a good surface appearance, but the coating film does not have great strength. Therefore, FRC films are easily susceptible to mechanical damage even though the coating material is cured. This damage can result in not only partial detachment of film, but also in large areas of delamination. There are many potential reasons; low temperature, low film thickness, or exceeding the recoating interval between the anti-corrosive and the tie coat/finish coat. It is crucial to carefully manage these variables before and after application.

Vessel Slippage

Vessel slippage on the support blocks in the dry dock during the block-build stage, and at the redocking stage, was shown to damage the FRC paint film. Initially, this vessel slippage was thought to be due to an uneven surface in the dock; however, the surfaces were found to be flat.

Vessel slippage was assessed in various tests. First, frictional resistance was evaluated with two coating schemes: a conventional SPC A/F coating and FRC (Table 1).

Test specimens were fully cured and then friction tests (based on a modified ice friction test for ice-going vessels) were carried out. In this test, the specimens were moved forward and backward horizontally under pressure, based on the yard practice, and the frictional resistance was measured. (The average support block pressure is about 40kg/cm².)

To mimic the support blocks used in prac-

tice, two types were mocked up for the resistance testing as shown in Figure 5. The block on the left is a new concept developed in an attempt to reduce mechanical damage of film. The block on the right is the general composition of support blocks used in the yard.

After the friction test, the SPC A/F was found to have a higher friction resistance than the FRC (Table 2). The tendency for mechanical damage is higher in the normal support block type than in new concept one (Fig. 6, p. 28).

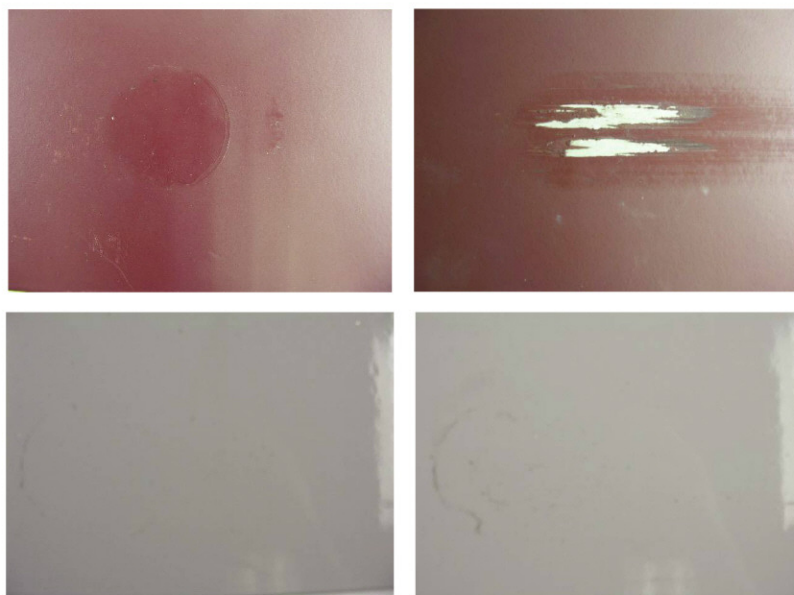

Fig. 6: Surface condition of each specimen with different support block: SPC A/F, new concept block (top left), SPC A/F, normal block (top right), FRC, new concept block (bottom left) and FRC, normal block (bottom right)

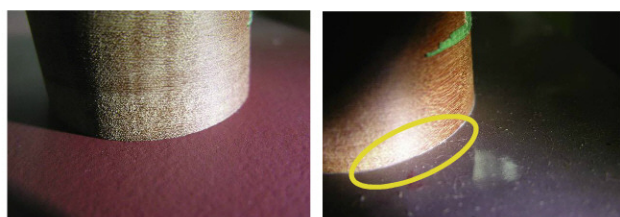

Fig. 7: Surface condition of each coating under loading; SPC A/F (left) and FRC (right)

The friction tests showed that FRC has a slippery surface, and how this contributes to film damage was further evaluated. The surface condition of the two paint systems was observed under load in the laboratory. The SPC A/F surface had no change before and after the load being applied, but in the case of the FRC, the coating film was squeezed out around the support block after loading. This might be caused by film properties due to the FRC film being very soft and slippery. The stress can be associated with thermal effects such as contraction or expansion from welding and fluctuation between day and night temperatures. Figure 7 shows the squeezed film, and Figure 8 illustrates the slippage theory of FRC.

In an effort to improve the support block composition and prevent slippage, we added a laminating film on the normal block in the dry dock stage, and inserted a cotton cloth between the hull and the block to increase friction resistance in the redock stage (Fig. 9). Since adopting these two methods, the slippage phenomenon has not occurred.

Conclusions

Regarding each potential issue discussed thus far, the following conclusions can be reached.

- It is impossible not to generate spray dust, but workers can minimize the quantity and spread of dust by using proper spray pressure on the pump and adequate containment at the work site.
- When FRC spray work is conducted in an enclosed place, a ventilation system should be considered.
- During FRC spray application, coating materials should be exposed to moisture for the shortest amount of time possible. It is very important to carefully inspect the substrate condition before coating application.
- In order to avoid film damage, application project supervisors should pay particular attention to environmental and drying conditions.
- The structure (or block) to which FRC is being applied might have propensity to slip, thus supporting material should be carefully considered.
- FRC is a product with novel technology and beneficial properties especially from an environmental point of view. However, to make effective use of this material, advanced application skills should be adapted to optimize its performance.

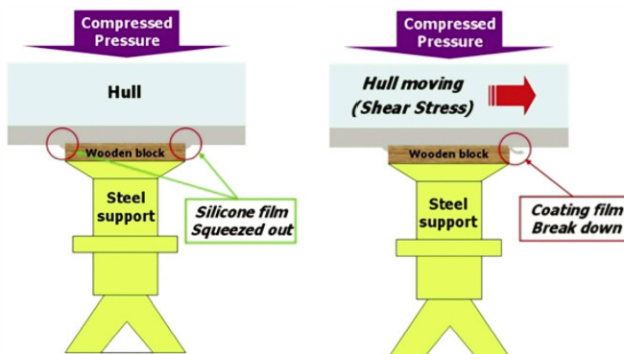

Fig. 8: The concept of slippage theory of FRC

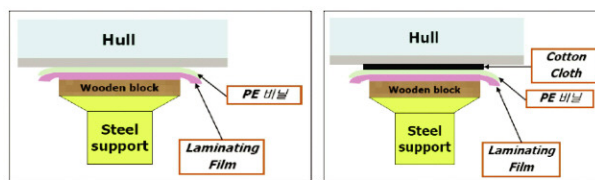

Fig. 9: Composition of support block in the dry dock stage (left) and the redock stage (right)

About the Authors:

Sang Ki Chi

Since September of 2002, Mr. Chi has been the senior research engineer in the coating and corrosion research department at the Institute of

Industrial Technology for Samsung Heavy Industries. His area of focus includes coating materials and application methods for marine and offshore field use.

Mr. Chi has received technical awards from The Society of Naval Architects of Korea and is a working group member of IMO for PSPC, and a member of The Corrosion Science Society of Korea. He holds a master's degree from Korea Maritime and Ocean University and a bachelor's degree from Pukyung National University, as well as certifications from FRO-SIO (Inspector Level 3) and ICorr (Fire Proofing Inspector Level 2).

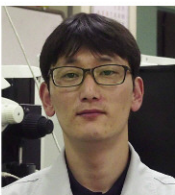

Seung Hyun Kim

Mr. Kim is a research engineer and has been with Samsung Heavy Industries for more than 18 years. His primary experience is with materi-

al analysis, carrying out performance testing of anti-corrosive and anti-fouling coatings as well as special materials for use in marine coatings.

Byung Wan Kim

Mr. Kim is an assistant engineer and has been with Samsung Heavy Industries for 10 years. His experience is in evaluation and testing

of materials for use in protective and marine coatings, as well as developing test equipment for special performance tests such as ice friction testing. JPCL

New

PosiTector[®] DPM Dew Point Meter

Advanced model shown with built-in probe

Measures and records environmental conditions

- Available with either a Built-in or Magnetic Separate probe and 2 models to choose from—Standard or Advanced
- All models include memory, statistics, USB port
- Auto Log mode—ideal for unattended operation
- Browse gage readings and charts using your computer's file explorer or upload to PosiTector.net
- **NEW** PosiTector body accepts all PosiTector DPM, SPG and 6000 probes easily converting from a dew point meter to a surface profile gage or coating thickness gage

2014 Equipment Buying Guide

The *JPCL* Equipment Buying Guide lists equipment and related supplies for protective and marine coating work from nearly 500 manufacturers, distributors, and rental companies, published annually to assist our readers in the identification of equipment and supplies for protective and marine coating operations.

On p. 32, you will find the Table of Contents, where generic products are listed under eight categories: Application; Climate Control; Climbing and other Access; Environmental Protection; Inspection; Laboratory Testing; Safety; and Surface Preparation.

On p. 33, you will find the Index to the Buying Guide, where products appear alphabetically in a single list. Individual company profiles with contact information can be accessed on p. 107.

In the Guide itself, which begins on p. 35, companies either displayed in boldface type or accompanied by boxed display ads have paid an advertising fee. Otherwise, a company's information appears free of charge.

The Guide is based on data obtained through a survey sent in April 2014 to manufacturers, distributors, and rental companies known to *JPCL*. The print edition of the *JPCL* Guide includes the companies that completed the survey by the deadline for the June 2014 issue. The Guide is also published at www.paintsquare.com, the online home of *JPCL*, where information is updatable throughout the year. To participate in the online edition of the Equipment Buying Guide between print editions, please contact Mark Davis at mdavis@paintsquare.com.

Products listed in the *JPCL* Equipment Buying Guide are in no way endorsed by *JPCL*, *PaintSquare*, or Technology Publishing Company.

DELONG IS YOUR SOLUTION FOR ALL **BLASTING APPLICATIONS**

Let DeLong Equipment Company have a technical representative assist you with any questions you have. From Virginia to Florida to Louisiana, DeLong is your solution for blasting applications. Call 800-548-8233 for the Atlanta location and 800-959-5009 for Greenville. We look forward to servicing you!

- 45 years of surface preparation, metal finishing and contractor industry experience

- Multiple locations ensure quick delivery

- Full line of Blast Pots, nozzles, valves, safety equipment and Blastrac equipment

- All abrasive types and sizes on hand

- Repair services and replacement parts

Excessive Humidity?

It's under control

With over fifty years of combined experience, **DH Tech** brings the best value in temporary climate control to the coatings industry. Innovative and resourceful approaches result in the most effective and economical solutions to humidity and temperature control. Manufactured in our Houston facility, **DH Tech** offers the most compact, durable and portable dehumidification, heating and cooling equipment available today. Our trained and qualified service team adds reliability and 24/7 response.

With **DH Tech** people and equipment on the job,
it's under control.

- Desiccant Dehumidification
- Cooling/Heating
- Application Design

24/7 on-call service

Small, Medium, Large?

ARID-Dry™ has a desiccant dehumidifier that's "Just Right" for your drying needs.

ARID-Dry has been delivering desiccant drying solutions for over 35 years with a range of desiccant systems from 600-27,500 SCFM in portable caster, trailer or skid mounted configurations. ARID-Dry products provide **temporary humidity control** for water damage and restoration, mold and fungus prevention, construction drying, industrial preparation and surface coatings as well as long term storage and layup with **drying results that are second to none.**

- ETL-C, ETL and CE Rated
- More capacity and power for your money
- Year round targeted drying results

Call 810.229.7900 or visit cdims.com today for a **ARID-Dry Accelerated Desiccant Drying System** that's "Just Right" for your drying needs.

Avoid Delays and Improve Your Bottom Line

Polygon's Engineered Heating and Dehumidification Solutions Deliver Real Benefits:

- Reduced operating cost.
- Lower equipment rental fees.
- Fit For Purpose Equipment for the Job.

Project Types Include:

- Climate control.
- Moisture control.
- Repair and Planned Maintenance.
- Heating and Cooling.

Response. Reliability. Results.

Don't drown under the pressure of costly delays; an engineered solution is just a call away.

Containment Tarps & Screens for Every Need

All painting and blasting contractors know how important reliability is to project success. So consider the 30 years of containment experience at Indian Valley Industries. We've got the specification know how and manufacturing processes that get you the containment tarps you're looking for.

Whether your project is large or small, we fabricate each tarp and screen with quality and efficiency, getting you what you need when you need it. We stock a wide range of fabrics that will meet or exceed your specification — impermeable, impenetrable, and permeable with or without fire resistance.

a **SPY** for every mission

Inspect Any Metal Surface Coating

For pipes, tanks or any coated contoured surface in the field or inside your manufacturing facility, we simplify coating integrity testing with our full line of SPY® portable and permanent Holiday Detectors.

SPY® Model 780, 785 and 790 Portable Holiday Detectors

- New ergonomic design
- Pipe coating inspections up to 60"
- Extremely durable
- Infinite voltage setting on the fly

Compact, lightweight wet sponge holiday detectors

SPY® Wet Sponge Portable Holiday Detectors

- No belts, lightweight, fast set up
- Sponge roller speeds large flat surface area inspections
- Interchangeable flat or roller sponge

Reliable continuous inspections on the assembly line

SPY® In-Plant Holiday Detector Systems

- Custom designed to streamline manufacturing
- From pipecoating inspections to large flat surfaces

Volume discounts on detectors available through our distributors. 4% for 6 through 10 detectors; 6% for 11 or more-same order same shipment. (excludes Model 670)

For more details on SPY® products and our complete line of SPY® Holiday Detection Equipment visit our website @ **www.pieltd.com**.

Unique, patented low temperature catalyst purifies compressed breathing air.

- for continuous use to remove carbon monoxide
- no expensive desiccant drying equipment needed
- helps provide comfortable, humidified compressed air to meet Grade-D requirements
- by far, the most economical CO-removal alternative

U.S. MINERALS

Service. Quality. Value.

With nationwide production and distribution capabilities, U.S. Minerals is capable of supplying a complete range of coal slag and other abrasives to meet all of your blasting requirements.

LOCATIONS

Anaconda, MT • Baldwin, IL • Coffeen, IL • Galveston, TX
Harvey, LA • La Cygne, KS • Roberts, WI

ADVANTAGES

- Less than 1% free silica
- Approved by California Air Resources Board*
- Passes TCLP (40 CFR 261.24a)
- Approved by U.S. Navy QPL (MIL-A-22262)*
- Chemically inert
- Hard, angular particles
- Very low friability
- Consistently uniform weight and gradation
- Licensed Blastox® Blender

Surface Technologies

Portable surface preparation systems supporting contractors all over the World.

Wet and dry blasting in one lightweight mobile unit.

Units available in 4 convenient sizes. Accessories include:
Compressors
Dust Reduction Vacuum
Lance Nozzle Extension
(for hard to reach places)
Rotational Nozzle
(for soft cleaning)

Water Jet Solutions

Productivity for sale or rent: HydroPrep™ tools

SRT-10 Crawler

Work high with no fall risk; wireless controls

Hand-held VertaJet™

Lightweight, with vacuum recovery

Vortex™

For floors, ship decks and more

NLB's HydroPrep® system lets you match tools to your surface prep jobs. Their rotating 40,000 psi water jets get down to bare metal (or concrete) quickly and leave a great surface for recoating.

From manual to fully automated, NLB accessories (and pump units) can make you more productive. You can rent or buy them at any of our six regional branches, or call 877-NLB-7989.

NLB Pump Unit

Easily converts to 8 pressures, up to 40,000 psi; 1,000 hp max.
